Preliminaries (skippable)

Model Editing (Knowledge Editing)

COLUMBIA | ENGINEERING
The Fu Foundation School of Engineering and Applied Science

- Model Editing (Knowledge Editing) aims to refine a pre-trained model by applying one or more edits, where each edit replaces a **factual association** (s, r, o) with new knowledge (s, r, o^*) ¹.

¹

Research Statement

To achieve this, **locating-and-editing** methods have been proposed for effective model updates. These methods typically follow three steps:

- **Step 1: Locating Influential Layers:** The first step is to identify the specific FFN layers that encode the target knowledge using causal tracing².

² References: [1] Meng, et al. Locating and editing factual associations in GPT. NeurIPS 2022

Preliminaries (skippable)

Model Editing (Knowledge Editing)

To achieve this, **locating-and-editing** methods have been proposed for effective model updates. These methods typically follow three steps:

- **Step 1: Locating Influential Layers:** The first step is to identify the specific FFN layers that encode the target knowledge using causal tracing³.

- **Clean run:** with prompt $s + r$.
- **Corrupted run:** obfuscated s randomly.
- **Restoration run:** restore embedding from clean run.

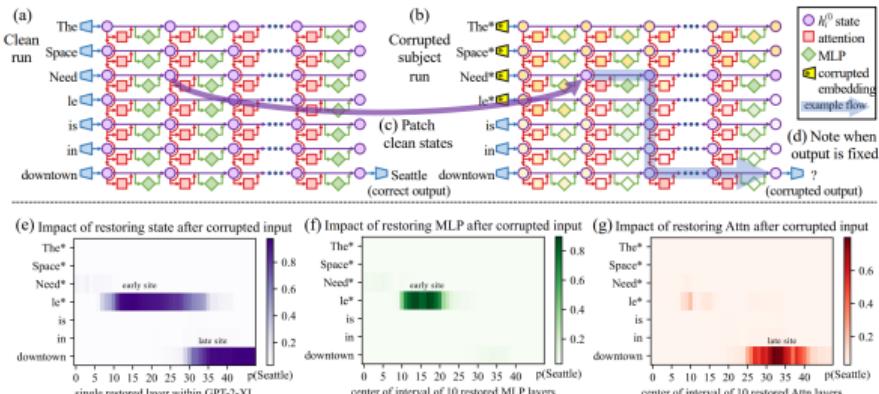

Figure 1: **Causal Traces** compute the causal effect of neuron activations by running the network twice: (a) once normally, and (b) once where we corrupt the subject token and then (c) restore selected internal activations to their clean value. (d) Some sets of activations cause the output to return to the original prediction; the light blue path shows an example of information flow. The causal impact on output probability is mapped for the effect of (e) each hidden state on the prediction, (f) only MLP activations, and (g) only attention activations.

Preliminaries (skippable)

Model Editing (Knowledge Editing)

- **Step 2: Acquiring the Expected Output:** The second step aims to obtain the desired output of the critical layers identified in Step 1.

- Following the **key-value theory**: the key k , which encodes (s, r) , is processed through the output weights W_{out}^l out to produce the original value v encoding o .

$$V = WK$$

Preliminaries (skippable)

Model Editing (Knowledge Editing)

COLUMBIA | ENGINEERING
The Fu Foundation School of Engineering and Applied Science

- **Step 2: Acquiring the Expected Output:** The second step aims to obtain the desired output of the critical layers identified in Step 1.
 - Following the **key-value theory**: the key k , which encodes (s, r) , is processed through the output weights W_{out}^l out to produce the original value v encoding o .

$$V = WK$$

- To perform editing, v is expected to be replaced with a new value v^* encoding o^* . To this end, current methods typically **use gradient descent on ΔW , maximizing the probability that the model outputs the word associated with o^*** ⁴.

$$V' = (W + \Delta W)K$$

⁴ References:[1] Meng, et al. Mass-editing memory in a transformer. ICLR 2023

Preliminaries (skippable)

Model Editing (Knowledge Editing)

COLUMBIA | ENGINEERING
The Fu Foundation School of Engineering and Applied Science

- **Step 3: Updating W_{out}^l** : This step aims to update the parameters W_{out}^l . It includes a factual set $\{\mathbf{K}_1, \mathbf{V}_1\}$ containing u new associations, while **preserving the set** $\{\mathbf{K}_0, \mathbf{V}_0\}$ containing n original associations. Specifically,

$$\begin{aligned}\mathbf{K}_0 &= [\mathbf{k}_1 \ \mathbf{k}_2 \ \cdots \ \mathbf{k}_n], & \mathbf{V}_0 &= [\mathbf{v}_1 \ \mathbf{v}_2 \ \cdots \ \mathbf{v}_n], \\ \mathbf{K}_1 &= [\mathbf{k}_{n+1} \ \mathbf{k}_{n+2} \ \cdots \ \mathbf{k}_{n+u}], & \mathbf{V}_1 &= [\mathbf{v}_{n+1}^* \ \mathbf{v}_{n+2}^* \ \cdots \ \mathbf{v}_{n+u}^*]\end{aligned}\tag{1}$$

Preliminaries (skippable)

Model Editing (Knowledge Editing)

COLUMBIA | ENGINEERING
The Fu Foundation School of Engineering and Applied Science

- **Step 3: Updating W_{out}^l :** This step aims to update the parameters W_{out}^l . It includes a factual set $\{\mathbf{K}_1, \mathbf{V}_1\}$ containing u new associations, while **preserving the set** $\{\mathbf{K}_0, \mathbf{V}_0\}$ containing n original associations. Specifically,

$$\begin{aligned}\mathbf{K}_0 &= [\mathbf{k}_1 \ \mathbf{k}_2 \ \cdots \ \mathbf{k}_n], \quad \mathbf{V}_0 = [\mathbf{v}_1 \ \mathbf{v}_2 \ \cdots \ \mathbf{v}_n], \\ \mathbf{K}_1 &= [\mathbf{k}_{n+1} \ \mathbf{k}_{n+2} \ \cdots \ \mathbf{k}_{n+u}], \quad \mathbf{V}_1 = [\mathbf{v}_{n+1}^* \ \mathbf{v}_{n+2}^* \ \cdots \ \mathbf{v}_{n+u}^*]\end{aligned}\tag{2}$$

Based on these, the **objective** can be defined as: ⁵

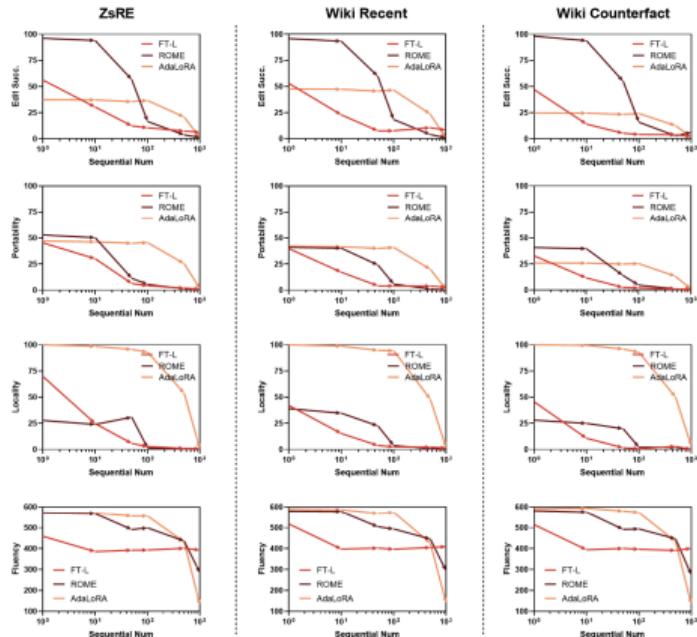

$$\tilde{\mathbf{W}}_{\text{out}}^l \triangleq \arg \min_{\hat{\mathbf{W}}} \left(\sum_{i=1}^n \|\hat{\mathbf{W}} \mathbf{k}_i - \mathbf{v}_i\|^2 + \sum_{i=n+1}^{n+u} \|\hat{\mathbf{W}} \mathbf{k}_i - \mathbf{v}_i^*\|^2 \right).\tag{3}$$

⁵ References:[1] Meng, et al. Mass-editing memory in a transformer. ICLR 2023

- Network generalization by alleviating redundancy through **angular diversification**.⁷

$$\min_{\mathcal{W}} \mathcal{L}(\mathcal{W}) \quad \text{s.t.} \quad 1 \leq i < j \leq m, \quad \left| \frac{\mathbf{w}_i \cdot \mathbf{w}_j}{\|\mathbf{w}_i\|_2 \|\mathbf{w}_j\|_2} \right| \leq \tau$$

- Why Does **Orthogonal Transformation** Make Sense?

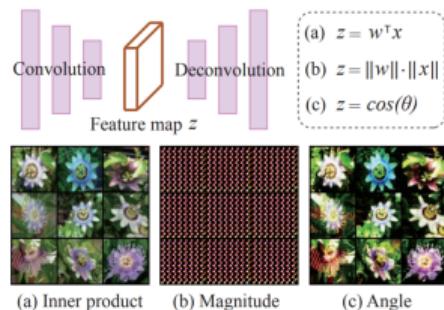

Figure 2: A toy experiment to demonstrate the importance of angular information. The autoencoder is trained in a standard way using inner product activation, and (a) shows the standard reconstruction. In testing, the angular information of neurons alone can well recover the input image, even if the autoencoder is not trained with angles.

⁷ References:[1] Xie, D. et al. Learning latent space models with angular constraints. In ICML, 2017. [2] Cogswell, Ahmed. et al. Reducing overfitting in deep networks by decorrelating representations. In ICLR, 2016. [3] Qiu, L. et al. Controlling Text-to-Image Diffusion by Orthogonal Finetuning. NeurIPS, 2023.

Research Questions

- 1. Does **knowledge editing** affect the **angular diversity** of edited weights?
- 2. Is there any correlation between **angular diversity** and {**editing**, **general task**} performance?
- 3. If **Yes**, is it possible to design an **angular diversity**-based regularization method to improve knowledge editing?

Before Introducing Correlation...

Mathematical Definition:

- **Hyperspherical Energy (HE)** quantifies the **uniformity of vector distributions on a hypersphere**.
- Given a normalized metric \mathbf{X} (focusing on angular aspect), the **HE** can be calculated by:

$$\text{HE}(\mathbf{X}) = \sum_{i \neq j} \left(\|\hat{\mathbf{x}}_i - \hat{\mathbf{x}}_j\|^2 + \epsilon \right)^{-s} = \sum_{i \neq j} \left(2(1 - \cos \theta_{ij}) + \epsilon \right)^{-s}$$

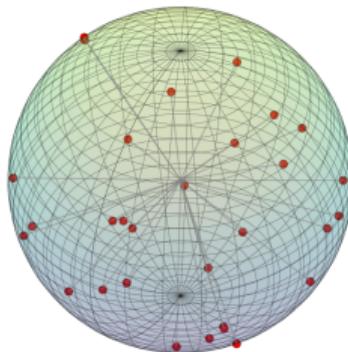

When vectors are close to **orthogonal** (around 90° apart), their **cosine similarity** diminishes toward 0, so this term approaches 1 and the overall **HE** decreases.

- **High HSE** → Vectors are **clustered** and non-uniformly distributed.
- **Low HSE** → Vectors are **well-dispersed** and uniformly distributed.

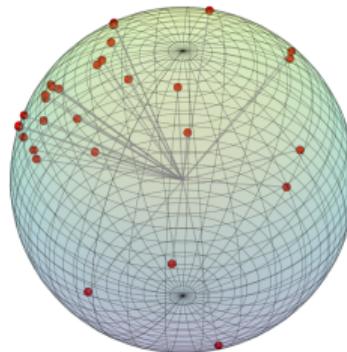

Before Introducing Correlation...

Mathematical Definition:

- **Hyperspherical Energy (HE)** quantifies the **uniformity of vector distributions on a hypersphere**.

(a) Weight Neurons (low HE)

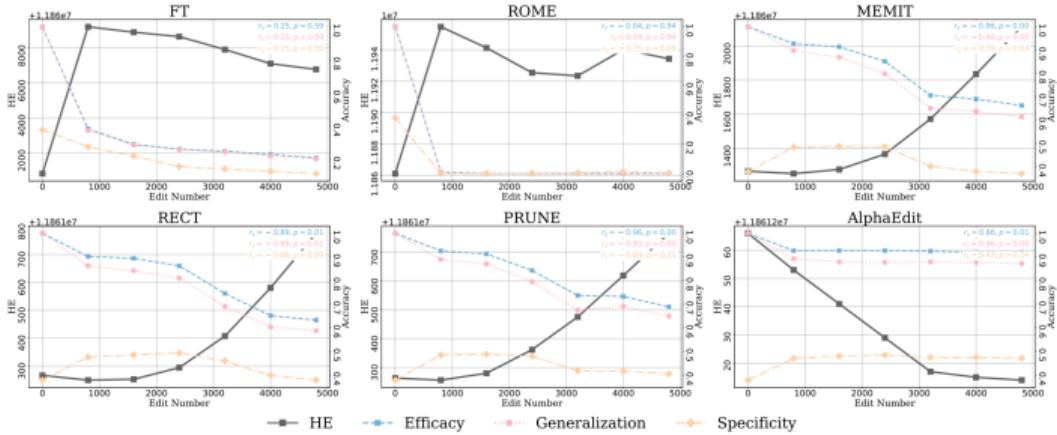

(b) Weight Neurons (high HE)

- **High HSE** → Vectors are **clustered** and non-uniformly distributed.
- **Low HSE** → Vectors are **well-dispersed** and uniformly distributed.

Research Questions

- 2. Does **knowledge editing** affect the **angular diversity** of edited weights?
- 3. Is there any correlation between **angular diversity** and {**editing**, **general task**} performance?

- **Observation 1: Collapse in sequential editing is closely tied to sharp fluctuations in HE.**

- **5,000 sequential edits with batch size of 100 on LLaMA3-8B.**

Figure 2: Trends of HE and editing performance throughout sequential editing. The Spearman correlation scores between HE and each editing metric displayed at the end of each curve.

- **Observation 2: Advanced editing methods suppress HE fluctuations effectively.**

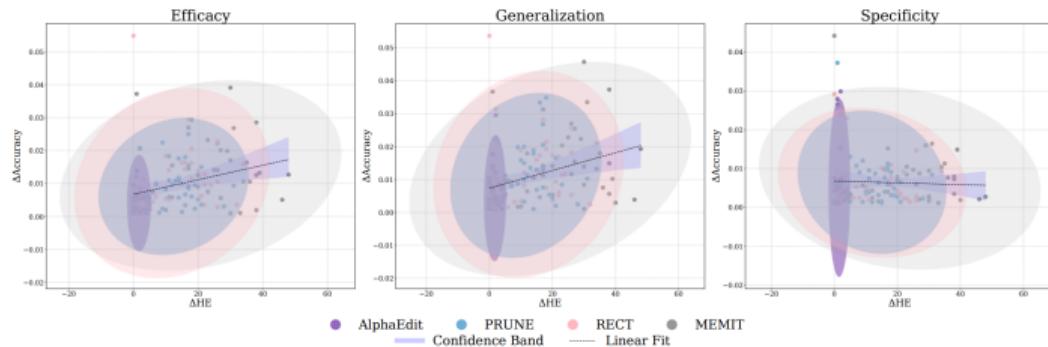

Figure 3: Correlation between changes in HE and editing performance across consecutive edited weights. Each point corresponds to a $\Delta HE - \Delta Acc$ pair for one method over five thousand sequential edits. Confidence ellipses and regression lines illustrate overall trends.

- The correlation between **changes in HE (HE)** and editing performance (**Acc.**), where **each point denotes the difference between two consecutive batch edits**.

- Theoretically: $|\Delta HE|$ is the lower-bound constraint for ΔV (disruption caused by editing).

$$\begin{aligned} \text{For } \Delta V &= (\mathbf{W} + \Delta \mathbf{W})\mathbf{K} - \mathbf{W}\mathbf{K} \\ &= \mathbf{W}\mathbf{K} + \Delta \mathbf{W}\mathbf{K} - \mathbf{W}\mathbf{K} \\ &= \mathbf{V} + \Delta \mathbf{V} - \mathbf{V} \\ &= \Delta \mathbf{V} \end{aligned}$$

which is the variation on the original knowledge (ΔV)

- Theoretically: $|\Delta\text{HE}|$ is the lower-bound constraint for $\Delta\mathbf{V}$ (disruption caused by editing).

$$\begin{aligned} \text{For } \Delta\mathbf{V} &= (\mathbf{W} + \Delta\mathbf{W})\mathbf{K} - \mathbf{W}\mathbf{K} \\ &= \mathbf{W}\mathbf{K} + \Delta\mathbf{W}\mathbf{K} - \mathbf{W}\mathbf{K} \\ &= \mathbf{V} + \Delta\mathbf{V} - \mathbf{V} \\ &= \Delta\mathbf{V} \end{aligned}$$

Theorem 1 (Lower Bound on Output Perturbation).⁸ Under the assumptions of orthonormal inputs and small perturbations, the output perturbation $\Delta\mathbf{V}$ is lower-bounded by squared change in HE:

$$|\Delta\mathbf{V}| \geq \left(\frac{\Delta\text{HE}}{K} \right)^2, \quad K = 4 \left(\sum_{k=1}^p \left(\sum_{j \neq k} \|\mathbf{w}_k - \mathbf{w}_j\|^{-3} \right)^2 \right)^{1/2}$$

where K is a constant dependent on the original weight matrix geometry.

⁸[1] NOTE: Detailed proof in our paper Section 3/Appendix in ENERGY-REGULARIZED SEQUENTIAL MODEL EDITING ON HYPERSPHERES:
<https://arxiv.org/abs/2510.01172>

Research Questions

- 3. If **Yes**, is it possible to design an **angular diversity**-based regularization method to improve knowledge editing?

- We introduce **SPHERE** (**S**parse **P**rojection for **H**yperspherical **E**nergy **R**egularized **E**ditting)

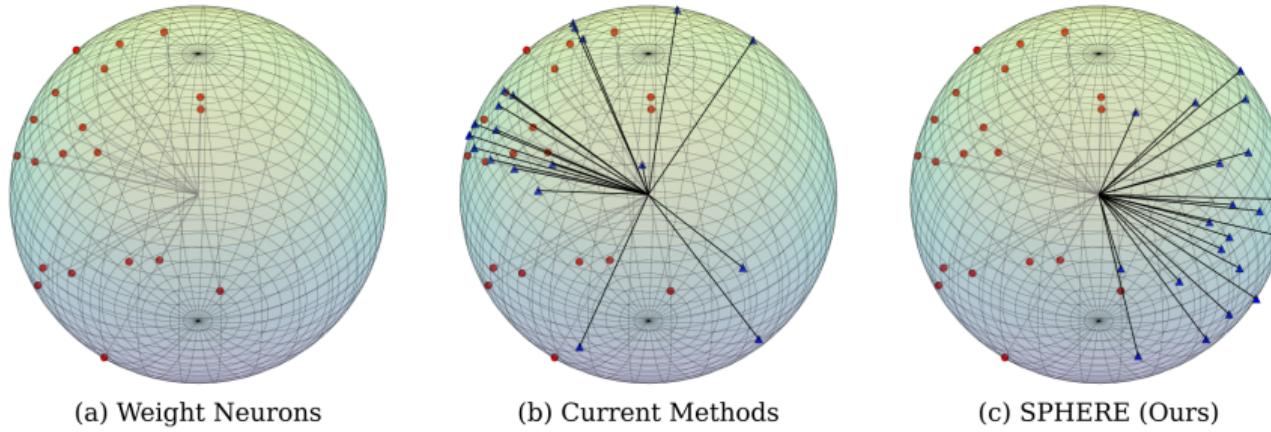

Figure 1: (a) A weight matrix is viewed as a set of neurons (red dots) on a hypersphere. (b) Current SOTA methods (Ma et al., 2025; Fang et al., 2025) introduce perturbations (blue triangles) that interfere with the principle hyperspherical directions of pre-edit weights. (c) SPHERE projects new knowledge onto a sparse space complementary to the principal hyperspherical directions.

- **1. Principal Space Estimation:** Estimate the principal space of \mathbf{W} via Rayleigh Quotient optimization.

$$\mathbf{v} = \arg \max_{\|\hat{\mathbf{v}}\|=1} \left(\frac{1}{n} \|\mathbf{W}\hat{\mathbf{v}}\|^2 \right) = \arg \max_{\|\hat{\mathbf{v}}\|=1} \left(\frac{1}{n} \hat{\mathbf{v}}^\top (\mathbf{W}^\top \mathbf{W}) \hat{\mathbf{v}} \right)$$

- **1. Principal Space Estimation:** Estimate the principal space of \mathbf{W} via Rayleigh Quotient optimization.

$$\mathbf{v} = \arg \max_{\|\hat{\mathbf{v}}\|=1} \left(\frac{1}{n} \|\mathbf{W}\hat{\mathbf{v}}\|^2 \right) = \arg \max_{\|\hat{\mathbf{v}}\|=1} \left(\frac{1}{n} \hat{\mathbf{v}}^\top (\mathbf{W}^\top \mathbf{W}) \hat{\mathbf{v}} \right)$$

According to the Rayleigh Quotient theory:

Key Insight

The maximum value of $Proj(\mathbf{v})$ is the largest eigenvalue of $\frac{1}{n} \mathbf{A}^\top \mathbf{A}$, and the corresponding direction \mathbf{v} is the **principal eigenvector**.

Then we can construct the principal subspace matrix based on the top- r eigenvectors of $\frac{1}{n} \mathbf{A}^\top \mathbf{A}$:

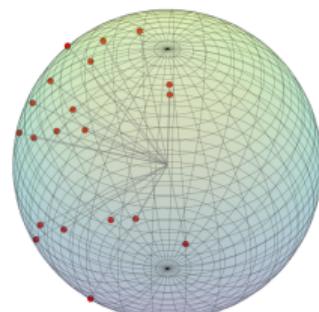

$$\mathbf{U} = [\mathbf{v}_{d-r+1}, \dots, \mathbf{v}_d] \in \mathbb{R}^{d \times r}$$

- 2. Sparse Space Definition:

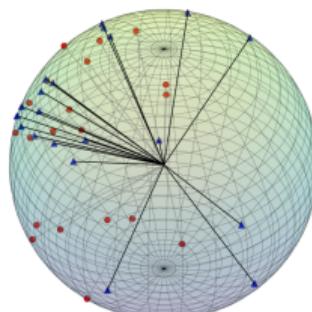

$$P_{\perp} = I - \alpha \mathbf{U} \mathbf{U}^{\top} \in \mathbb{R}^{d \times d}$$

- 3. Sparse Space Definition:⁹

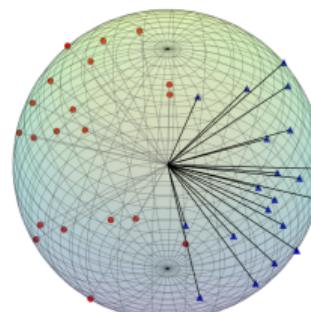

$$\hat{\mathbf{W}} = \mathbf{W} + \Delta \mathbf{W}_{\text{proj}} = \mathbf{W} + \Delta \mathbf{W} P_{\perp}$$

(a) Weight Neurons

(b) Current Methods

(c) SPHERE (Ours)

⁹ References: [1] we also provide a mathematical proof that SPHERE suppresses the HE, ensuring bounded variations in the hidden representations $\Delta \mathbf{V}$: see Appendix C.2 in our paper: <https://arxiv.org/abs/2510.01172>

Research Questions

- **RQ1:** How does SPHERE perform on sequential editing **compared to baseline** methods?
- **RQ2:** Can SPHERE effectively **preserve the hyperspherical uniformity** of edited weights?
- **RQ3:** How does SPHERE-edited LLMs perform on **general ability** evaluations?
- **RQ4:** Can baseline methods be significantly improved with **plug-and-play SPHERE?**

- **RQ1:** How does SPHERE perform on sequential editing tasks **compared to baseline** methods?

Table 1: Comparison of SPHERE with existing methods on sequential editing. *Eff.*, *Gen.*, *Spe.*, *Flu.* and *Consis.* denote Efficacy, Generalization, Specificity, Fluency and Consistency, respectively. The best results are highlighted in bold, while the second-best results are underlined.

- **15,000 edits on LLaMA3 (8B), 5,000 edits on Qwen2.5 (7B).**
- SPHERE achieves substantial gains in both **Efficacy** and **Generalization**, with average improvements of **24.19%** and **16.02%**, respectively, over the best baseline.

- RQ2: Can SPHERE effectively **preserve the hyperspherical uniformity** of edited weights?

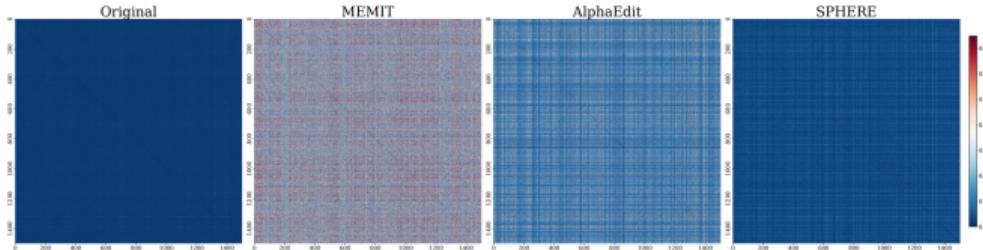

Figure 4: Cosine similarity between neurons in the updated weight matrix after 15,000 edits. Darker colors indicate lower similarity, reflecting better hyperspherical and orthogonal uniformity. SPHERE effectively preserves the weight structure, demonstrating the most stable hyperspherical uniformity.

- SPHERE effectively preserves hyperspherical uniformity after editing, as the **cosine similarity** among weight neurons remains **close to the original distribution**, thereby avoiding directional collapse.

- **RQ2:** Can SPHERE effectively **preserve the hyperspherical uniformity** of edited weights?

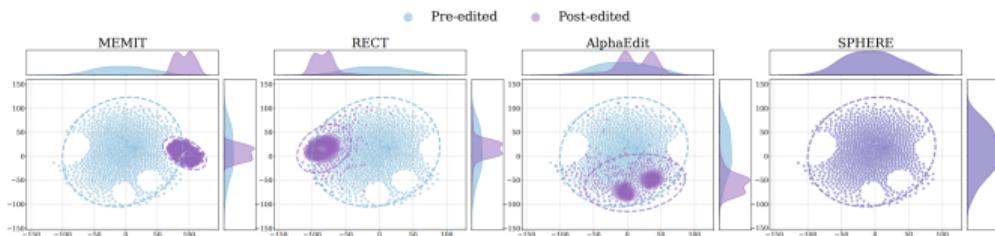

Figure 5: The t-SNE distribution of weight neurons of pre-edited and post-edited LLM after 15,000 edits using dimensionality reduction. The top and right curve graphs display the marginal distributions for two reduced dimensions, where SPHERE consistently exhibits minimal shift.

- The pre- and post-edited weights exhibit **nearly overlapping distributions**, indicating that SPHERE prevents significant shifts in weights and maintains consistency.

- **RQ3:** How does SPHERE-edited LLMs perform on **general ability** evaluations?

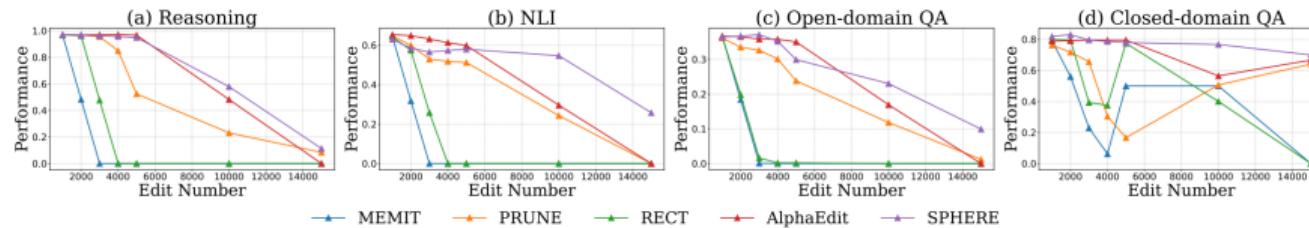

Figure 6: General ability testing of post-edited LLaMA3 (8B) on four tasks.

- **Four representative tasks** were adopted following RECT¹⁰, including **Reasoning** on GSM8K, **Natural Language Inference (NLI)** on RTE, **Open-domain QA** on Natural Questions, and **Closed-domain QA** on BoolQ.
- SPHERE effectively **preserves the general abilities** of post-edited LLMs even under extensive editing, maintaining the original model performance across all metrics **after 15k edits**.

¹⁰ References:[1] Model Editing Harms General Abilities of Large Language Models: Regularization to the Rescue

- **RQ4:** Can baseline methods be significantly improved with **plug-and-play SPHERE?**

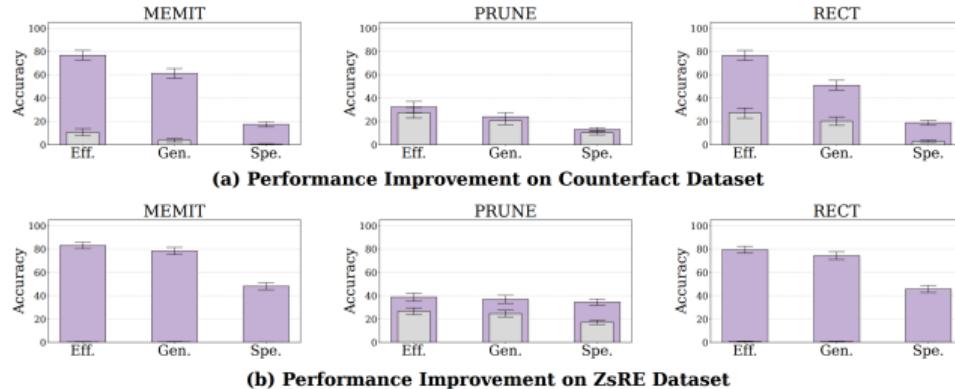

Figure 7: Performance improvements of baseline editing methods after adding a single line of code from SPHERE (i.e., sparse space projection). Gray bars denote the original baseline performance, while purple bars indicate the performance after enhancement.

- On average, the optimized baselines achieve relative improvements of **49.05%**, **42.64%**, and **24.44%** in **Efficacy**, **Generalization**, and **Specificity**, respectively **after adding a single line of code from SPHERE (i.e., sparse space projection)**.

Analysis of SPHERE

- **RQ4:** Can baseline methods be significantly improved with **plug-and-play SPHERE?**

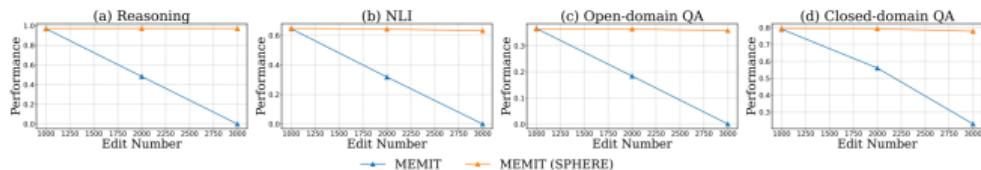

Figure 10: General ability improvements of MEMIT after incorporating SPHERE with a single line of sparse space projection code.)

■ The baselines enhanced with the SPHERE projection also demonstrate **significantly better robustness in general abilities.**

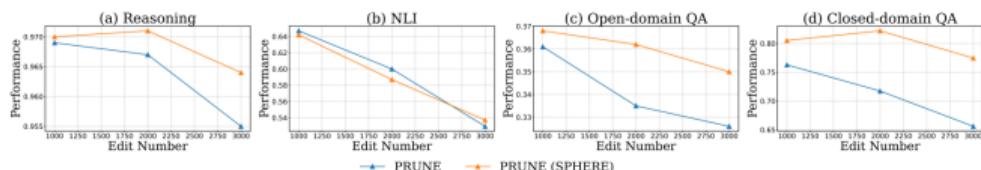

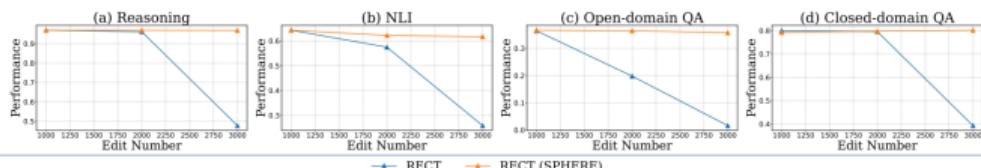

Figure 11: General ability improvements of PRUNE after incorporating SPHERE with a single line of sparse space projection code.)

- Most studies calculate the **adjacency matrix** by directly memorizing the data, such as **distance-** and **correlation**-based matrices.
- These adjacency matrices ignore potential distribution shifts between training and test data, leading to the **Out-of-Distribution (OOD)** generalization problem.

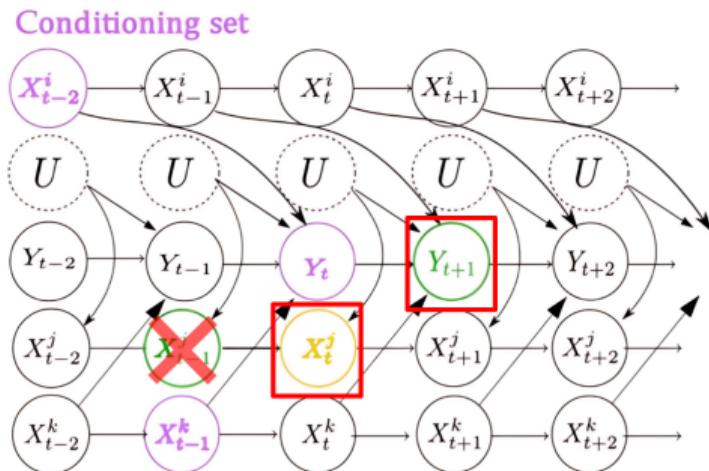

- Most studies calculate the **adjacency matrix** by directly memorizing the data, such as **distance-** and **correlation**-based matrices.
- These adjacency matrices ignore potential distribution shifts between training and test data, leading to the **Out-of-Distribution (OOD)** generalization problem.

Research Question

Can we find the underlying causal relations in temporal dimension to enhance the prediction on learned graph?

- Kernel-based Conditional Independence Test (CIT) —identifies dependencies among **temporal variables** via kernel similarity measures.
- Systematic Path Isolation (SyPI)¹¹: filters out **spurious or fake relations** discovered by the kernel-based CIT.

$$X_t^j \not\perp\!\!\!\perp Y_{t+1} | X_{t-2}^i, X_{t-1}^k, Y^t \quad (1)$$

$$X_{t-1}^j \perp\!\!\!\perp Y_{t+1} | X_t^j, X_{t-2}^i, X_{t-1}^k, Y^t \quad (2)$$

$\not\perp\!\!\!\perp$: dependent

$\perp\!\!\!\perp$: independent

¹¹ References: [1] Necessary and sufficient conditions for causal feature selection in time series with latent common causes, ICML 2021

- **Key idea:** Replace the traditional adjacency matrix with a **learned causal adjacency matrix** to address the **Out-of-Distribution (OOD)** issue.

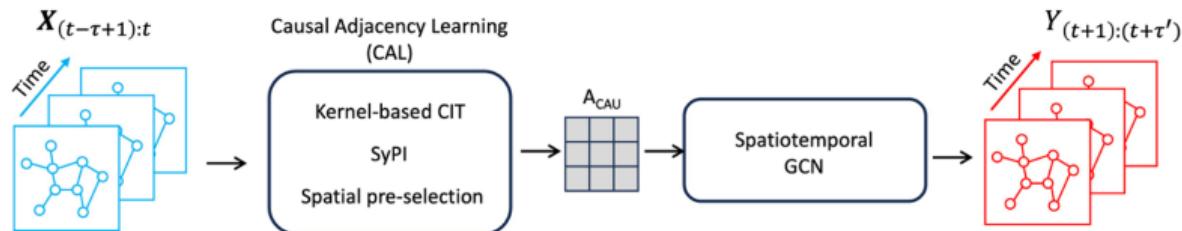

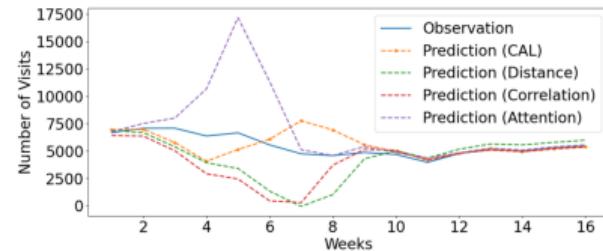

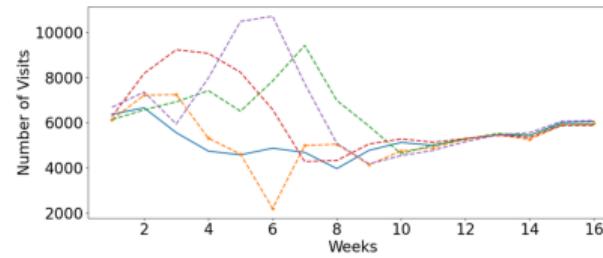

Fig. 1: Framework of the upstream CAL and the downstream spatiotemporal GCN for the problem of STPG.

Experiment

Compared with our **distance**-, **correlation**-, and **attention**- based baseline matrix, the CAL algorithm has a better performance in predicting the OOD dataset, particularly for **long-term predictions**.

(a) Predict next 1 week (ZIP = 10309)

(b) Predict next 4 week (ZIP = 10309)

- **CAL method** achieves **14.23%, 15.49%,** and **50.27%** RMSE improvement in predicting the **next week's mobility** in New York, compared with **distance-, correlation-,** and **attention-** based adjacency matrices, respectively.

TABLE II: Performance metrics of GCN prediction on future 1-4 weeks based on different adjacency matrices. Bolded represents the best result and underlined means second best.

#Adjacency	RMSE/MAE

*Equal contributions

- **Goal:** To address the **Out-of-Distribution (OOD)** problems in vision models.
- In the **MNIST_Colored** dataset, the training set contains digits **0–4** in red and **5–9** in green, while the test set reverses this color mapping (**0–4** in green, **5–9** in red).

MNIST_Colored Dataset (Training set)

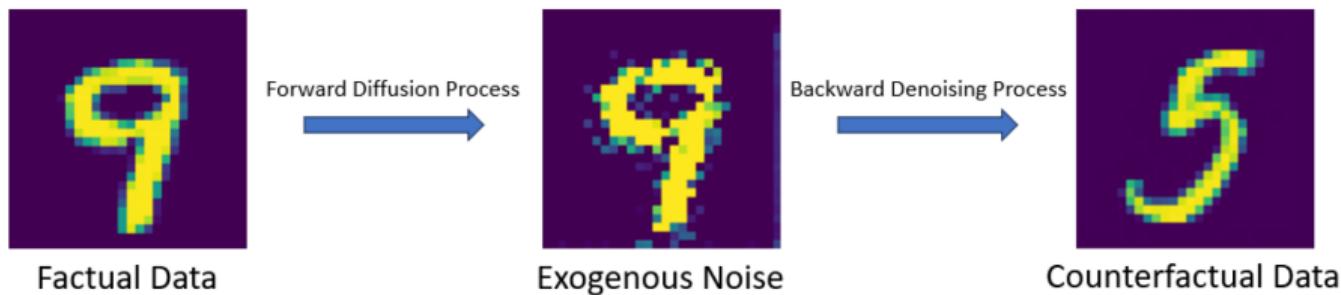

- **Goal:** To address the **Out-of-Distribution (OOD)** problems in vision models.
- In the **MNIST_Colored** dataset, the training set contains digits **0–4** in red and **5–9** in green, while the test set reverses this color mapping (**0–4** in green, **5–9** in red).

MNIST_Colored Dataset (Training set)

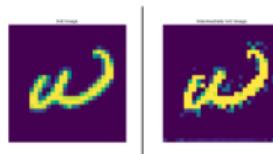

- Due to the OOD issue, it is **challenging to use supervised models effectively**. To address this, we aim to generate **counterfactual data** e.g., a red "5" or a green "0" to augment the training set and improve generalization.

- Previous work (**Diff-SCM**)¹² has introduced **counterfactual estimation** by firstly inferring **latent variables** with deterministic forward diffusion, then intervening on a reverse diffusion process using the **gradients of an anti-causal** predictor w.r.t the input.

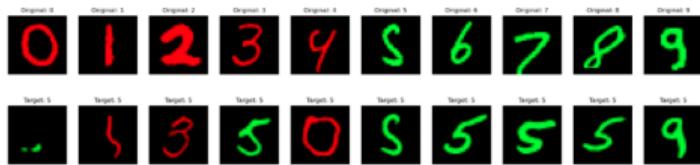

¹² References:[1] Diffusion Causal Models for Counterfactual Estimation, ICLR 2022

- However, Diff-SCM doesn't work well on **OOD** datasets due to issues in the forward diffusion process. The difference between exogenous noise and original data is too small, and the model fails to generate counterfactual data.

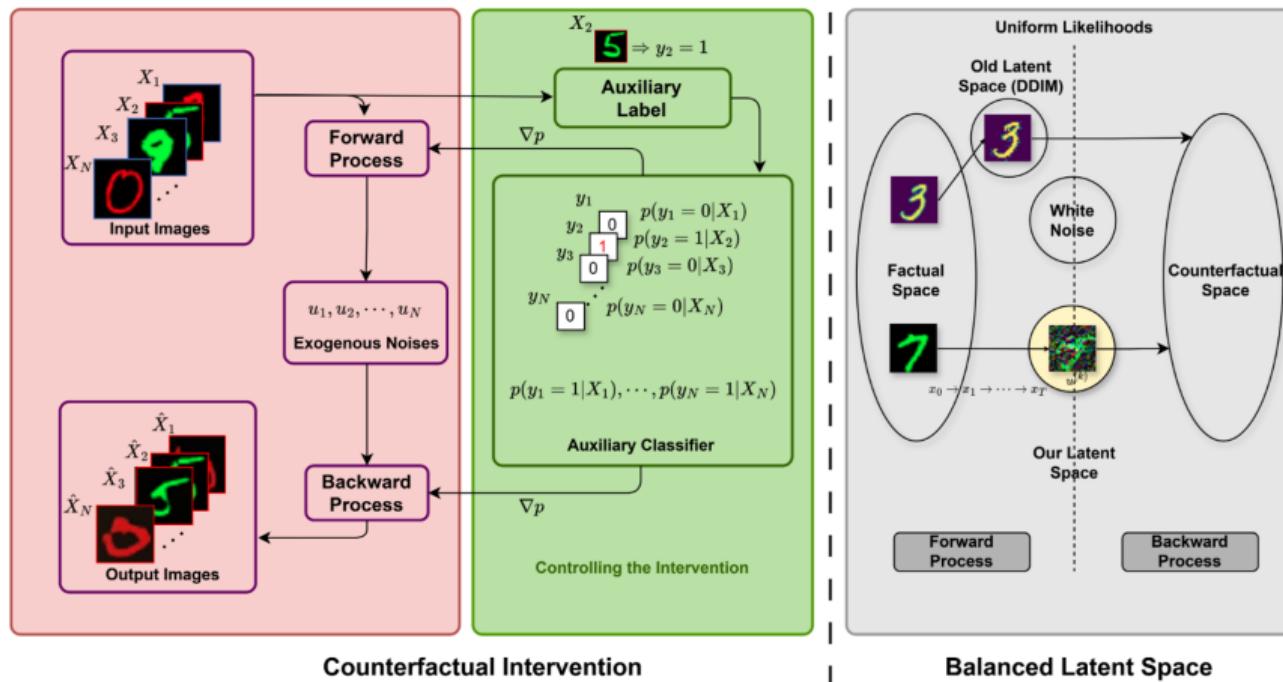

Forward process of the Diff-SCM

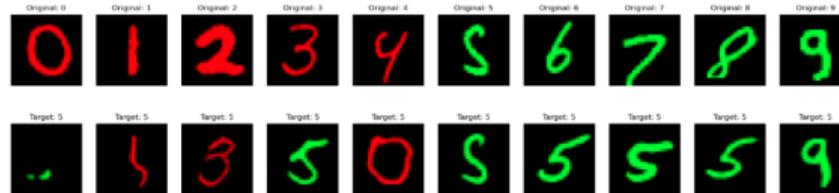

Left: original digit ($T = 0$). **Right:** Exogenous noise ($T = 1000$)

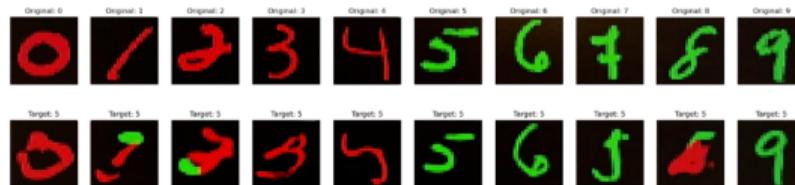

Diff-SCM on MNIST_Colored dataset. It fails to generate red digit "5".

Experiment & Ablation Study

Generation results with old latent space

Generation results with new latent space. Note that the red "5" is **strongly OOD**.

Title: Directional-Diffusion-Models-via-Fourier-Transform

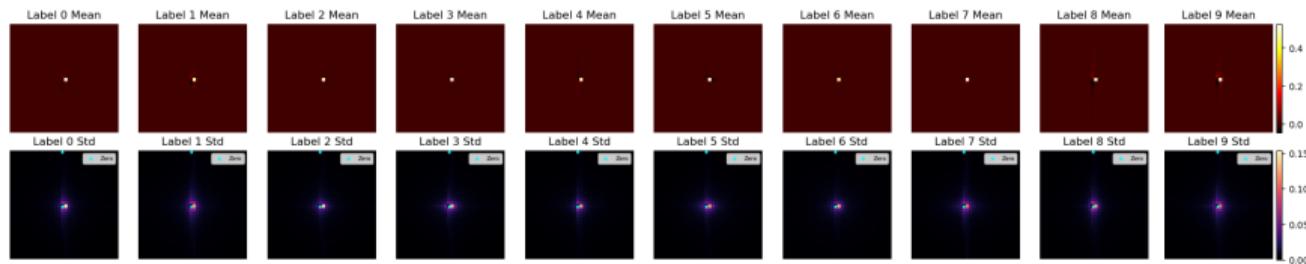

On Going Project: The research is expected to be submitted to **CVPR 2026**

Affiliations: DitecT Lab, Columbia University

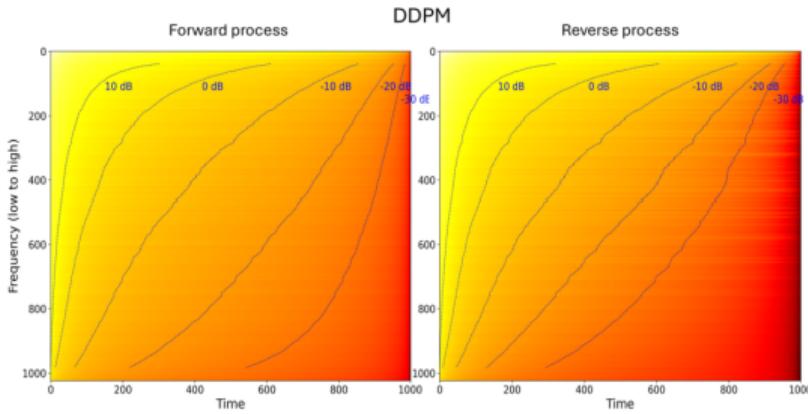

*Equal contributions

- We find that there exists a frequency component **invariant** across all classes (CIFAR10 dataset).

- Existing approaches **fail to maintain frequency consistency, with high-frequency** components deteriorating significantly faster than low-frequency ones as reflected by a steeper decline in SNR over time.

DDPM: High frequencies are corrupted substantially faster (SNR changes more per time increment) than low frequencies.

What is DIRE? And what is DIREs role in AI-Synthetic Detection?

- Diffusion Reconstruction Error (DIRE) helps distinguish between **human-generated** and **diffusion-generated** content.
- It measures the **difference between the input frame and its reconstruction** from a diffusion model:

$$DIRE(x_0) = |x_0 - \mathbf{R}(\mathbf{I}(x_0))|$$

● x_g : Generated

○ x_r : Real

● x'_g : Reconstructed generated

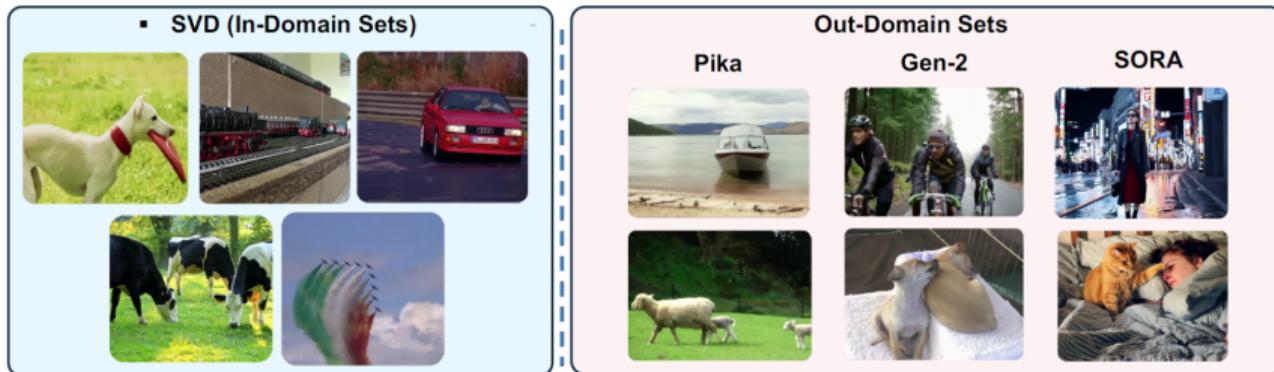

○ x'_r : Reconstructed real

Preliminaries

Diffusion Reconstruction Error (DIRE)

- **Real** video frames are sampled from **YouTube**, while **synthetic (fake)** videos come from **SORA** by OpenAI.
- The **reconstructed** frame of a **SORA-generated** video is visually **closer** to the input frame, whereas the **real** video from **YouTube** are not (e.g., distorted cat face).

	Video Source	Denoising Condition	Generated Model	# of Clips (real/fake)
In-domain	VidVRD [18]	Image2Video	SVD-XT [9]	2k/2k
Out-domain	VidVRD (test) VidVRD (test) YouTube/SORA [6]	Image2Video Image2Video x	Pika [2] Gen-2 [3] x	107/107 107/107 207/191

Method

DIVID: Diffusion-based Video Detection

■ The Flow of DIVID

- Given a sequence of video frames, we first **generate the reconstructed version** of each frame using a diffusion model.
- Compute the DIRE** (Diffusion Reconstruction Error) between each reconstructed frame and its input, revealing the reconstruction discrepancy.
- A **CNN+LSTM** detector jointly models RGB frames and DIRE sequences to classify videos as **Real or Synthetic**.

Experiment & Ablation Study

	Detector Architecture	Evaluation Metrics	
		Acc.	AP
RGB	CNN	90.16	97.02
RGB	CNN+LSTM	90.16	97.39
DIRE [22]	CNN	92.74	97.46
DVID/ DIRE only	CNN+LSTM	93.68	97.66
DVID/ DIRE + RGB	CNN+LSTM	91.33	98.20

	Model	Out-domain			Total Avg.
		Gen-2	Pika	SORA	
RGB	CNN	65.42	78.04	60.05	67.84
RGB	CNN+LSTM	67.76	84.11	60.80	70.89
DIRE [22]	CNN	50.93	60.75	54.77	55.48
DVID / DIRE only	CNN+LSTM	60.75	80.37	60.8	67.3
DVID / DIRE + RGB	CNN+LSTM	66.82	86.92	61.01	71.58

- DVID achieves **98.20%** average precision (AP) and has better detection accuracy, and outperforms them by **0.94%** to **3.52%**.
- On three **out-domain** test sets, including **SORA**, **Pika**, and **Gen-2**. DVID improves the out-domain average accuracy by **0.69%** to **16.1%**.

Motivation

Agentic LVLM Framework for Diffusion-Generated Video Detection

- Deep Learning based detection frameworks always faced with limitations like **transparency**, **inability to recognize new artifacts**

- We proposed an **self-evolving LVLM Framework** for Diffusion-Generated Video Detection with explicit knowledge enhancement.

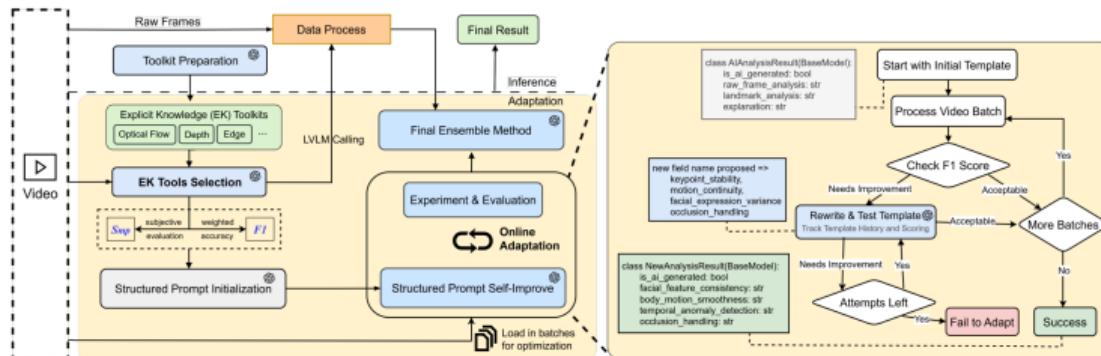

Figure 2. An agentic framework (**LAVID**) for video detection. The left part shows our main pipeline. First, LVLMs suggest tools relevant to video detection, and based on the model's preferences and the performance improvement each tool provides, we assemble a customized toolkit for each LVLM for video detection. The right part shows the details of the online adaptation for structured prompt. The prompt tuning will be based on the LVLM itself. Component marked with the logo  are developed with the LVLM like GPT-4o [41].

- We create a new benchmark called VidForensic which features 200 text-to-video prompts and more than **1.4k** high-quality videos, collected or generated from **eight generative models**.

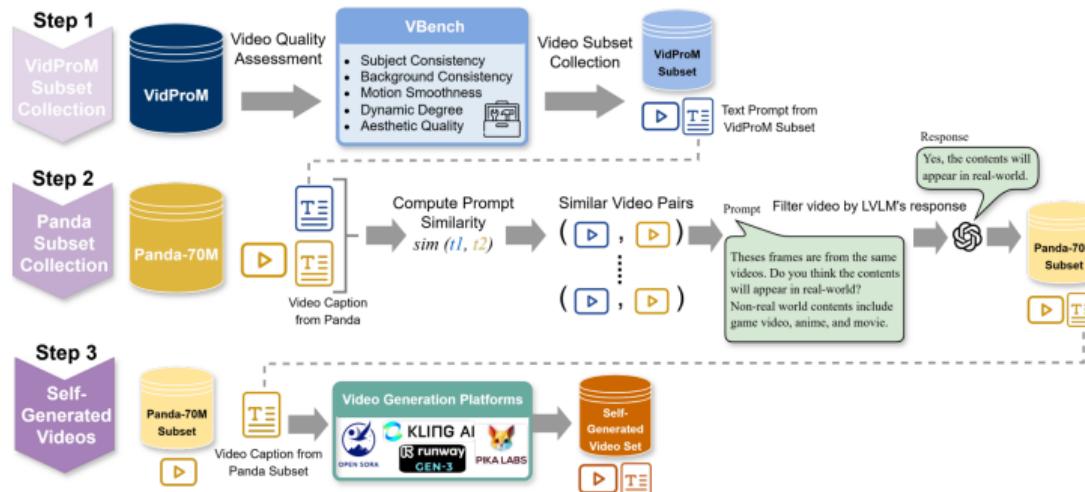

Figure 6. Dataset collection pipeline for VidForensic. Component marked with the logo are developed with the LVLM like GPT-4o [41].

- Evaluation results show that LAVID improves F1 scores by **6.2 to 30.2%** over the top baselines on our benchmark across four SOTA LVLMs, including Llava, Qwen-VL, Gemini-1.5-pro, GPT-4o.
